## 3. WEB COMPONENTS

*Web Components* are a set of W3C standards that enable the creation of reusable widgets or components in Web documents and Web applications. Web components aim to bring *Component-Based Software Development* (CBSD) to the World Wide Web. Some advantages of CBSD approach are reusability, replacability, extensibility, encapsulation and independence.

## 4. LINKED DATA-DRIVEN WEB COMPONENTS

We define a *Linked Data-driven* (LD-R) Web Component as a Web component that employs RDF data model for representing its content and specification (i.e. metadata about the component).

### 4.1 Features

Linked Data-driven Web components provide the following features:

- *Fine-grained Web applications.* Resource Description Framework (RDF) provides a common data model that allows data-driven components to be created, shared and integrated in a structured way across different applications. Figure 1 depicts the 5 main component

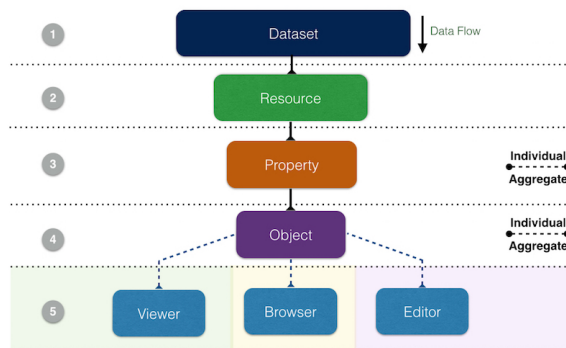

Figure 1: Architecture of LD-R Applications.

levels in a Linked Data-driven Web application. The dataflow in the application starts from the *Dataset* component which handles all the events related to a set of resources embedded in a named graph. The next level is the *Resource* component which is identified by a URI and indicates what is described in the application. A resource is specified by a set of properties which are handled by the *Property* component. Properties can be either individual or aggregate when combining multiple features of a resource. Each property is instantiated by a value (or multiple values in case of an aggregate object). The values of properties are controlled by the *Object* component which invokes different components to view, edit and browse the property values. *Viewer*, *Editor* and *Browser* components are terminals in the LD-R single directional data flow where customized user-generated components can be plugged into the system.

In addition to the fine-grained component architecture, LD-R Web applications provide a fine-grained access control over the data provided by the components. RDF-based access control in LD-R applications operates at four different granularities provided by Dataset, Resource, Property and Object component levels. For example, we can restrict access to a specific property of a specific resource in a certain dataset.

- *Customization and Personalization.* LD-R provide a versatile approach for context adaptation. A context can be a specific domain of interest, a specific user requirements or both. In order to enable customization and personalization, LD-R exploits the concept of

Figure 3: Life-cycle

*Scope.* A scope is defined as a directed combination of Dataset, Resource, Property and Object components (cf. Figure 2). Each scope conveys a certain level of specificity on a given context ranging from 1 (most specific) to 15 (least specific). For example, on the property level, we can define a generic configuration for all properties and then for some specific properties within a specific resource, we can change or overwrite those configurations.

Scopes can be defined under a specific user which facilitates versioning and reuse of user-specific configs. User-specific scopes provide different views on components and thereby data, based on the different personas dealing with those components.

- *Component/Content Visibility and Reusability.*  
- RDFa, Microdata

We would like to thank our colleagues from the KRR research group at VU University Amsterdam for their helpful comments during the development of the LD-R framework. This work was supported by a grant from the European Union's 7th Framework Programme provided for the project RISIS (GA no. 313082).
